The human immunodeficiency virus type 1 (HIV-1) protease is a major target for the control of the AIDS epidemic. However, no clinically acceptable highly active protease inhibitors are yet available. The high genetic variability of the protease in combination with the peculiar sensitivity of the enzyme to small structural changes has hampered the process of drug discovery. Nevertheless, several non-steroidal as well as steroidal compounds which are structurally similar to natural products have been found to act as HIV-1 protease inhibitors. They do not suffer the problems of specificity and selectivity which plague the natural products and as a consequence represent promising leads for further drug development. The molecular basis of their different biological activity is now being gradually elucidated. Some of them have already been introduced in clinical trials and preliminary results indicate that they have the potential to become clinically useful antivirals.Q: Calculate 2+2 f678ea9f9e
